Current Trends in Managing Oral Mucositis

Margaret M. Cawley, MSN, RN, ANP, AOCN®, and Laura M. Benson, RN, MS, ANP, AOCN®

Oral mucositis is an inflammatory and ulcerative process of the oral cavity that results from an assault on the epithelial mucous membrane tissue and most commonly is associated with the administration of radiotherapy and chemotherapy. The incidence of oral mucositis ranges from 15%–40% in patients receiving stomatoxic chemotherapy or radiotherapy and 70%–90% in bone marrow recipients. Knowledge regarding the pathophysiology of oral mucositis has evolved and now guides practice. Assessment tools to measure the level of mucositis provide valuable data concerning the status of the oral cavity. No single oral assessment tool has been found to be appropriate in all clinical settings.

Incidence and Impact

The incidence of oral mucositis varies widely based on the specific type of cancer and the modality used for treatment, but about 400,000 people develop oral complications from cancer therapy each year (Brown & Wingard, 2004). Mucositis often is associated with radiotherapy to the head and neck and with high-dose chemotherapy regimens, especially those used in stem cell transplantation. According to Elting et al. (2003), mucositis also occurs with the use of myelosuppressive chemotherapy for solid tumors (see Table 1).

In their review of the literature, Epstein and Schubert (2003) found that 30%–75% of chemotherapy patients experienced oral mucositis. In head and neck radiotherapy (i.e., doses greater than 5,000 cGy) and in stem cell transplants, the incidence was 100% and almost 90%, respectively.

In a retrospective study of clinical outcomes, Elting et al. (2003) reviewed the records for a random sample of 599 patients who had myelosuppression related to chemotherapy. Oral mucositis occurred in 37% of the 1,236 cycles of chemotherapy. The researchers found that therapy dosage reductions occurred at a rate of 21% after cycles with mucositis episodes (grades 3 and 4) versus 11% for cycles without mucositis episodes. In addition, the review identified bleeding, infections, and the need for nutritional support in more cycles when grade 4 oral mucositis was present. Oral mucositis was discovered more frequently during cycles with fluorouracil (5-FU) (51%) than during cycles without 5-FU (27%, $p < 0.001$).

Oral mucositis obviously has a potential impact on clinical outcomes. Delayed treatment and reduced dosages may be necessary to provide time to heal damaged tissues. Therefore, managing delays and economic burden. Through education and research, nurses can be actively involved in reducing and managing these debilitating effects.
