Psychological Functioning, Post-Traumatic Growth, and Coping in Parents and Siblings of Adolescent Cancer Survivors

Andrea M. Turner-Sack, PhD, Rosanne Menna, PhD, Sarah R. Setchell, PhD, Cathy Maan, PhD, and Danielle Cataudella, PsyD

Since the 1980s, the incidence rates of childhood and adolescent cancer have increased and the mortality rates have decreased in the United States and Canada (National Cancer Institute, n.d.; National Cancer Institute of Canada, 2008). This has resulted in a growing population of young cancer survivors with a unique set of psychological issues. Researchers have explored some of these issues, including survivors’ moods, anxieties, and coping strategies (Dejong & Fombonne, 2006; Schultz et al., 2007; Turner-Sack, Menna, Setchell, Mann, & Cataudella, 2012). However, the focus is often on the negative aspects of childhood cancer, such as depression, with fewer studies addressing a more positive aspect, such as positive changes in perspectives, life priorities, and interpersonal relationships (Kamibeppu et al., 2010; Seitz, Besier, & Goldbeck, 2009). In addition, the experiences of young cancer survivors’ families often are ignored.

### Purpose/Objectives
To examine psychological functioning, post-traumatic growth (PTG), coping, and cancer-related characteristics of adolescent cancer survivors’ parents and siblings.

### Design
Descriptive, correlational.

### Setting
Children’s Hospital of Western Ontario in London, Ontario, Canada.

### Sample
Adolescents who finished cancer treatment 2–10 years prior (n = 31), as well as their parents (n = 30) and siblings (n = 18).

### Methods
Participants completed self-report measures of psychological distress, PTG, life satisfaction, coping, and cancer-related characteristics.

### Main Research Variables
Psychological functioning, PTG, and coping.

### Findings
Parents’ and siblings’ PTG levels were similar to survivors’ PTG levels; however, parents reported higher PTG than siblings. Parents who used less avoidant coping, were younger, and had higher life satisfaction experienced less psychological distress. Parents whose survivor children used more active coping reported less psychological distress. Siblings who were older used more active coping, and the longer it had been since their brother or sister was diagnosed, the less avoidant coping they used.

### Conclusions
Childhood and adolescent cancer affects survivors’ siblings and parents in unique ways.

### Implications for Nursing
Relationship to the survivor, use of coping strategies, life satisfaction, and time since diagnosis affect family members’ postcancer experiences.
