New Options for Metastatic Breast Cancer

Debra K. Frye, RN, BSN, OCN®, CCRP, Suzanne M. Mahon, RN, DNSc, AOCN®, APNG, and Frances M. Palmieri, RN, MSN, OCN®, CCRP

Patients with advanced breast cancer are living longer and receiving multiple lines of chemotherapy; however, they eventually develop resistance to the agents. Two more agents have been approved for the treatment of breast cancer and will provide additional treatment options for such patients. Ixabepilone represents a new class of cytotoxic chemotherapy called the epothilones. Ixabepilone was approved for use as a single agent for the treatment of metastatic breast cancer resistant to taxanes, anthracyclines, and capecitabine, as well as in combination with capecitabine for disease refractory to taxanes and anthracyclines. Bevacizumab, a monoclonal antibody targeting vascular endothelial growth factor, was approved for first-line treatment of HER2-negative metastatic breast cancer in combination with paclitaxel. Understanding the efficacy, toxicity, and administration of the agents is crucial for oncology nurses to optimally educate and treat patients with advanced breast cancer.

Ixabepilone

Ixabepilone represents a novel class of cytotoxic chemotherapy, the epothilones. Epothilones exert their cytotoxic effect by binding to and stabilizing microtubules (Goodin, Kane, & Rubin, 2004), which are cellular components that have several functions crucial to cell division and growth. In a manner similar to taxanes, when bound to microtubules, epothilones disrupt their function (Goodin et al.). Evidence exists that epothilones have activity in taxane-resistant cancer cells (Goodin et al.). Other epothilones are in development, but ixabepilone is the first agent in the class to receive FDA approval. It is approved for use as a single agent for the treatment of MBC resistant to taxanes, anthracyclines, and capecitabine, as well as in combination with capecitabine for disease refractory to taxanes and anthracyclines.

At a Glance

- Metastatic breast cancer responds to multiple types of therapies, but drug resistance remains a clinical challenge.
- Ixabepilone, a first-in-class epothilone, recently was approved for use in patients with resistant breast cancer.
- Bevacizumab has been approved for use in combination with paclitaxel for upfront use in metastatic breast cancer.

Debra K. Frye, RN, BSN, OCN®, CCRP, is a research nurse manager in the Department of Breast Medical Oncology at the University of Texas M.D. Anderson Cancer Center in Houston; Suzanne M. Mahon, RN, DNSc, AOCN®, APNG, is a clinical professor in the Department of Internal Medicine and in the School of Nursing at Saint Louis University in Saint Louis, MO; and Frances M. Palmieri, RN, MSN, OCN®, CCRP, is a clinical nurse specialist manager in the breast clinic and breast cancer program at Mayo Clinic in Jacksonville, FL. Frye is a member of the speakers bureau for Bristol-Myers Squibb Company and Genomic Health and is a consultant for Bristol-Myers Squibb Company. Publication of this supplement is made possible through an unrestricted educational grant from Bristol-Myers Squibb. Mention of specific products and opinions related to those products do not indicate or imply endorsement by the Clinical Journal of Oncology Nursing or the Oncology Nursing Society.
