A Feasibility Study of Low-Cost, Self-Administered Skin Care Interventions in Patients With Head and Neck Cancer Receiving Chemoradiation

Catherine Marie Mannix, RN, MSN, OCN®, Marian Mahin Bartholomay, RN, MSN, AOCN®, Carol S. Doherty, RN, BSN, OCN®, Maryellen Lewis, RN, BSN, OCN®, and Mary-Liz Connors Bilodeau, RN, MS, CCRN, ACNP-BC

Nurses from radiation oncology, ambulatory infusion, and inpatient oncology units perceived an increase in skin toxicities in patients receiving chemoradiation within their respective clinical settings. The group formed a skin care task force (SCTF) and was joined by a nurse practitioner from the ambulatory burn clinic who had previously consulted on patients with treatment-related toxicities. The SCTF’s preliminary work identified several areas for improvement. Nurses were using a variety of tools from the Radiation Therapy Oncology Group (RTOG) and National Cancer Institute (NCI), as well as descriptive documentation, to measure and describe grades of toxicity, including the RTOG skin toxicity tool and the NCI’s Common Terminology Criteria for Adverse Events (CTCAE), version 3.0.

Current evidence for the management of radiation skin toxicities demonstrates equivocal outcomes using a variety of interventions, leaving substantial gaps in knowledge. Skin toxicities can lead to treatment delays, infection, pain, and increased costs for the patient. Patients with head and neck cancers receiving chemoradiation (N = 100), a population particularly vulnerable to disruptions in skin integrity, were enrolled into a prospective, descriptive study. Data collection was conducted and photographs were taken at baseline and weekly throughout treatment. Patients received skin care kits, instructions, and a diary to record adherence. Skin toxicity was measured and validated by at least three observers using serial photographs with 100% interrater agreement. Data were analyzed using descriptive statistics, graphs, and bivariate analysis. Adherence to both washing and moisturizing was consistently high. Although a correlation existed between the radiation dose and skin toxicity at week 6, no correlation existed between skin toxicity and adherence. Given the rate of grade 3 toxicities at week 6 and product costs, this proved to be an affordable regimen to which patients could easily adhere. Positive patient outcomes can be promoted through teaching and reinforcement of self-care measures to reduce skin toxicity.

No standard skin care regimen was used to minimize or prevent treatment-related skin toxicities. This resulted in inconsistent management and prevention of treatment-related skin toxicities. The SCTF also surveyed staff regarding the wide range of skin care products used and found that the products varied in cost, availability, and evidence of efficacy.

To address these problems, the SCTF proposed using a standardized tool (see Figure 1) that would promote consistent skin toxicity grading across settings, implement an algorithm for management of skin toxicities to establish guidelines, and encourage consistent skin care across settings. In addition, an evidence-based literature review was conducted to determine best practice. The literature review revealed insufficient and inconclusive evidence supporting use of specific products;
