Experiences of Women With Gestational Trophoblastic Neoplasia Treated With High-Dose Chemotherapy and Stem Cell Transplantation: A Qualitative Study

Kam Singh, RN, MSc, Clare Warnock, RN, MSc, Jane Ireson, MA, RN, Sarah Strickland, RN, BSc Hons, Delia Short, Michael J. Seckl, PhD, FRCP, and Barry W. Hancock, MD, FRCP

Singh is a lead nurse, Warnock is a practice development sister, and Ireson is a clinical nurse specialist, all at Sheffield Teaching Hospitals in South Yorkshire, England; Strickland is a clinical nurse specialist and Short is a specialty manager, both at the Imperial College NHS Foundation Trust in London, England; Seckl is a professor of medical oncology in the Department of Surgery and Cancer at Imperial College in London; and Hancock is a retired professor emeritus in the Medical School at the University of Sheffield in South Yorkshire.

Purpose/Objectives: To explore the experiences of women with gestational trophoblastic neoplasia during and after treatment to understand their perspectives, priorities, and concerns.

Research Approach: A descriptive, exploratory study using in-depth semistructured interviews.

Setting: All interviews were conducted in a quiet, designated room at Weston Park Hospital in Sheffield, South Yorkshire.

Participants: Women with gestational trophoblastic neoplasia who had received stem cell transplantation from 2003 to 2013. Ten patients were eligible, and eight agreed to participate.

Methodologic Approach: Interviews were carried out over the phone and were recorded and transcribed verbatim. Framework analysis was carried out to generate in-depth descriptions of participants’ experiences.

Findings: Participants described significant physical, psychological, and social effects during and following treatment. Recovery was slow, and treatment had long-term effects on sexuality and body image. The impact of the women’s diagnosis and treatment on their children was a primary concern.

Interpretation: The study provided insight into the multidimensional impact of stem cell transplantation, which can continue after treatment. The need for family-centered services for patients with dependent children was identified.

Implications for Nursing: Nurses need to develop services that effectively communicate the challenges of stem cell transplantation to patients and provide family-centered care and late effects and rehabilitation services.

Women receiving high-dose chemotherapy with stem cell transplantation for gestational trophoblastic neoplasia (GTN) face unique challenges associated with a rare cancer diagnosis that requires arduous treatment and an uncertain outcome. The purpose of the study was to explore the experiences of women with GTN following high-dose chemotherapy with stem cell transplantation to understand their perspectives, priorities, and concerns.

Gestational trophoblastic disease (GTD) comprises a group of pregnancy-related tumors arising from the trophoblastic tissue, one of which is called a hydatidiform mole (complete or partial). The worldwide incidence of GTD varies considerably; in the United Kingdom, the incidence of GTD is about 1.5 per 1,000 live births, and the incidence in the United States is similar (Choi, Lee, Smith, & Kim, 2015). In most cases, GTD presents as a benign tumor, but malignant change occurs in about 15% of complete moles and in 0.5%–1% of partial moles (Choi...
