Medical Cannabis

The oncology nurse’s role in patient education about the effects of marijuana on cancer palliation

Carey S. Clark, PhD, RN, AHN-BC

BACKGROUND: Cannabis, also known as marijuana, is legal either medicinally or recreationally in most of the United States, with 60% of the United States population residing in these states (Kasai & Trumble, 2017). Oncology nurses may have a special interest in assisting patients with using cannabis as a palliative treatment, because patients with cancer should be offered early palliation in support of better cancer treatment outcomes (Howie & Peppercorn, 2013). However, most nurses have received minimal education on how cannabis works in the body and on the nature of the oncology nurse’s emerging role in guiding patients’ use of cannabis for palliation. This article will briefly review the body’s endocannabinoid system (ECS), explore how the oncology nurse can support patient use of cannabis as a palliative option, discuss cannabis ingestion and delivery methods, and note the proper dosing of cannabis for patients with cancer.

The Basics of the Endocannabinoid System: Cannabis as Medicine

Nurses are ethically obligated to ensure patients’ autonomy, and the ethical standards for nurses require that high-quality care be provided to all patients, including those who use cannabis for palliation. To best advise patients with cancer about the use of cannabis as a palliative medicine, nurses must have basic knowledge of the body’s ECS. Although the ECS was discovered in the mid-1990s by Raphael Mechoulam, an Israeli organic chemist and professor of medical chemistry, it is not standard content in nursing curricula.

METHODS: This article examines the literature and uses a theoretical-conceptual method to explore the oncology nurse’s role in supporting the use of medicinal cannabis by patients with cancer.

FINDINGS: The oncology nurse can play a pivotal role in supporting patients’ use of cannabis for palliation.
