Perceptions of Support Among Older African American Cancer Survivors

Jill B. Hamilton, PhD, RN, Charles E. Moore, MD, Barbara D. Powe, PhD, RN, Mansi Agarwal, MPH, and Pamela Martin, PhD

Patients diagnosed with cancer are living longer. An estimated 11 million cancer survivors are alive in the United States today, and the five-year survival rate for some cancers is as high as 90% (American Cancer Society [ACS], 2010). Cancer survival rates for African Americans also are improving. Since the 1960s, the overall five-year survival rate for African Americans has more than doubled, from 27% to 58% (ACS, 2010). Although these figures show that survival disparities are diminishing, African Americans continue to suffer disproportionately from cancer as they continue to have more advanced disease (ACS, 2010), less access to timely treatments and quality care (Shavers & Brown, 2002), and more comorbidities (Bryant & Cerfolio, 2008). This cancer burden is compounded by a social environment in which social stigma and fatalistic attitudes toward cancer are prevalent (Phillips, Cohen, & Moses, 1999; Powe & Finnie, 2003) and in which healthcare institutions discriminate against the poor and minorities (Burgess, Ding, Hargreaves, van Ryn, & Phelan, 2008; Hausmann, Jeong, Bost, & Ibrahim, 2008). When a diagnosis of cancer is confirmed, African Americans experience a myriad of supportive and unsupportive responses from family and friends (Grange, Matsuyama, Ingram, Lyckholm, & Smith, 2008). These responses are critical because they may affect whether survivors are adherent to recommended treatment and affect their overall quality of life during the cancer experience. However, researchers have not fully explored older African American cancer survivors’ perceptions of their social support and the implications of these needs on their survivorship experiences.

The purpose of this study was to explore the social support needs from the perspective of older African Americans diagnosed with and treated for cancer. African Americans’ involvement in mutual aid systems of giving and receiving support makes them an exemplary population for studying supportive relationships (Hamilton & Sandelowski, 2004). Their unique experiences in collectively pooling resources to meet their needs, coupled with their experiences of having the highest overall incidence and lowest survival rates of any racial or ethnic group (ACS, 2010) provide the opportunity to analyze the complexity of supportive social relationships among this population.
