Steroid-Associated Side Effects in Patients With Multiple Myeloma: Consensus Statement of the IMF Nurse Leadership Board

Beth Faiman, RN, MSN, APRN, BC, AOCN®,
Elizabeth Bilotti, RN, MSN, APRN, BC, OCN®, Patricia A. Mangan, APRN, BC,
Kathryn Rogers, RN, and the IMF Nurse Leadership Board

Steroids have been the foundation of multiple myeloma therapy for more than 30 years and continue to be prescribed as single agents and in combination with other antmyeloma drugs, including novel therapies. Steroids cause a wide range of side effects that affect almost every system of the body. Identification and prompt management of the toxicities contribute to the success of steroid-containing antmyeloma regimens. By following patients carefully and educating them and their caregivers, nurses can promote adherence to therapy and improve quality of life. The International Myeloma Foundation’s Nurse Leadership Board developed this consensus statement for the management of steroid-associated side effects to be used by healthcare providers in any medical setting.

Glucocorticosteroids or corticosteroids, referred to in this article as steroids, include dexamethasone, prednisone, and prednisolone. The agents have been a backbone of therapy for multiple myeloma since the late 1960s (Alexanian et al., 1969), followed by the use of dexamethasone in combination therapy and as a single agent in the 1980s and 1990s (Alexanian, Dimopoulos, Delasalle, & Barlogie, 1992). The novel immunomodulatory drugs lenalidomide (Revlimid®, Celgene Corporation) and thalidomide (Thalomid®, Celgene Corporation) are indicated with concomitant dexamethasone (Celgene Corporation, 2007a, 2007b). The proteasome inhibitor bortezomib (Velcade®, Millennium Pharmaceuticals, Inc.), although indicated as a single agent, also may be administered in combination with dexamethasone (Millennium Pharmaceuticals, Inc., 2007).

Steroids can cause a wide range of adverse events that affect almost every system of the body (Merck & Co., Inc., 2004; Tariman & Estrella, 2005; Watson Laboratories, Inc., 2006). Identification and prompt management of the toxicities, as well as patient and caregiver education, are vital to the success of steroid-containing antmyeloma regimens. In recognition of the need for specific recommendations on managing key side effects of steroid therapy for patients with myeloma, the International Myeloma Foundation’s Nurse Leadership Board developed this consensus statement for the management of steroid-associated side effects to be used by healthcare providers in any medical setting (Bertolotti et al., 2007, 2008).

Issue Statement

Dexamethasone and prednisone inhibit the expression of cytokines (e.g., interleukin-6), which are major growth factors for...
myeloma cells, and reduce the activity of nuclear factor-kappa B, leading to apoptosis (programmed cell death) (Alexanian et al., 1992; Berenson et al., 2002). However, steroids can adversely affect multiple body systems; have a significant impact on patients’ physical, social, and psychological functioning; and result in decreased quality of life and reduced treatment adherence. Adverse effects can lead to less effective dosing, which has a negative impact on treatment and survival outcomes. The management strategies described in this article may increase treatment adherence, which may result in optimal therapy responses and improved quality of life.

Strategic Recommendations

- Medical personnel should be aware of the potential side effects of steroid therapy on multiple body systems.
- Nurses should assess all patients by taking a history, performing a physical examination, and reviewing medications.
- Patients and their families should be educated about the potential side effects of steroid therapy.
- Nurses and patients’ families should apply appropriate interventions if the side effects occur.
- Patients should understand the importance of informing their healthcare providers about all medications, including over-the-counter herbs and vitamins, and not self-medicating without consulting the healthcare team.

Toxicity Tool for Grading and Managing Adverse Events

Figure 1 outlines the steroid-related side effects that patients with multiple myeloma receiving steroid-based therapy are likely to experience. The severity of the adverse events can be quantified and assigned a grade of severity through the National Cancer Institute (NCI) Common Terminology Criteria for Adverse Events (CTCAE). Table 1 lists NCI CTCAE version 3.0 toxicity grades for adverse events that correspond to the steroid side effects listed in Figure 1. The grades may be used for monitoring steroid-related toxicities, researching, and determining the need for and types of interventions. The grades also allow for consistency of evaluation among healthcare providers, which is important for patients who need referral to specialists for management of steroid-related side effects. For each system, pharmacologic, nonpharmacologic, and educational strategies are recommended as appropriate.

Constitutional Signs and Symptoms

"Let down" effect: This usually is characterized by fatigue or “weakness” and myalgia following discontinuation of steroids. It may occur when patients are receiving high-dose steroids (e.g., dexamethasone) several days each week. Pharmacologic interventions include low-dose steroids for a few days following high-dose steroid administration, tapered doses of steroids, and reduced steroid doses. Figure 2 presents a suggested dexamethasone taper schema. However, dose reductions for dexamethasone should be based on the clinician’s experience and the patient’s symptoms. Reducing the dose of dexamethasone may reduce the risk of thromboembolic events, particularly if administered in combination with other antimaloma agents, such as lenalidomide and thalidomide (Rome et al., 2008). Patients should be advised about adjusting their activity schedules to deal with associated fatigue (Mitchell, Beck, Hood, Moore, & Tanner, 2006).

Flushing or sweating: When flushing or sweating occur, comorbid conditions such as infection, cardiovascular abnormalities, and hypertension should be ruled out by appropriate assessments and laboratory tests. Perimenopause in women should be ruled out by appropriate assessments and laboratory tests for hormonal status, if indicated. Nonpharmacologic interventions include patient education about using cold cloths and ice packs, maintaining hydration, and layering clothes.

Insomnia: Patients may benefit from altering the timing of medications (e.g., taking steroids in the morning so they wear off by evening). Pharmacologic interventions include hypnotics and sedatives; the drug class of choice should be determined by the grade of insomnia as well as the type of insomnia (e.g., difficulty falling asleep versus difficulty staying asleep). Nonpharmacologic interventions include evaluation of sleep habits and education regarding sleep hygiene (e.g., taking a warm bath before bed, not watching television or reading in bed) (Page, Berger, & Johnson, 2006). In addition to steroid-related insomnia, other causes of sleeplessness in patients with

Select agitation, anxiety, depression, or euphoria.

Note. Based on information from National Cancer Institute, 2006.
myeloma should be considered, such as pain and obstructive sleep apnea, which may result from steroid-related weight gain. Nurses should ask patients what keeps them up at night and whether they have trouble falling asleep or staying asleep. The questions will help to identify whether insomnia is steroid-related or caused by a different issue.

**Sexual Dysfunction**

In men, rule out other causes by checking testosterone levels and evaluate for neuropathy and other comorbidities. Evaluate for pharmacologic interventions, including hormone supplementation if needed, and phosphodiesterase-5 inhibitors if indicated. Nonpharmacologic interventions include patient education and support as deemed advisable by the clinician and possible referral to a urologist if pharmacologic interventions fail (National Library of Medicine & National Institutes of Health, 2007). Patients and their families should receive counseling and education regarding the potential for steroid-associated mood changes that may be severe. Referrals to support groups and psychosocial services (e.g., social worker, psychiatrist) should be considered. Pharmacologic interventions include dose reduction and discontinuation of steroids and dosing in the morning versus later in the day. The use of selective serotonin reuptake inhibitors or mood stabilizers (e.g., citalopram, escitalopram, olanzapine) may help not only with mood alterations but also with insomnia and hyperactivity (Badger, Fulcher, Gunter, Mars, & Reese, 2006; Cerullo, 2006).

**Psychiatric Signs and Symptoms**

- **Personality changes or mood alterations:** Patients should be evaluated with a predetermined depression tool (MacArthur Initiative on Depression and Primary Care, 2003–2006; National Institutes of Mental Health, 2007). Patients should be asked about suicidal ideation. Patients and their families should receive counseling and education regarding the potential for steroid-associated mood changes that may be severe. Referrals to support groups and psychosocial services (e.g., social worker, psychiatrist) should be considered. Pharmacologic interventions include dose reduction and discontinuation of steroids and dosing in the morning versus later in the day. The use of selective serotonin reuptake inhibitors or mood stabilizers (e.g., citalopram, escitalopram, olanzapine) may help not only with mood alterations but also with insomnia and hyperactivity (Badger, Fulcher, Gunter, Mars, & Reese, 2006; Cerullo, 2006).

*Note.* Based on information from National Cancer Institute, 2006.
If a patient's white blood cell count is elevated, ask about and assess for any signs or symptoms of infection or the use of granulocyte growth factors. Patients should be educated to be aware of signs and symptoms of infection. Pharmacologic interventions include prophylaxis and treatment with antibacterial, antiviral, or antifungal agents.

**Hyperactivity:** Nonpharmacologic interventions include patient education regarding taking steroids in the morning, avoiding divided doses, and negotiating activity schedules to correspond with energy levels. In addition to altering medication schedules, relaxation techniques and exercise may be effective in decreasing hyperactivity. Pharmacologic interventions include benzodiazepines and mood stabilizers (Cerullo, 2006).

**Immune System Signs and Symptoms**

**Leukocytosis:** If a patient’s white blood cell count is elevated, ask about and assess for any signs or symptoms of infection or the use of granulocyte growth factors. Patients should be educated to be aware of signs and symptoms of infection. Pharmacologic interventions include prophylaxis and treatment with antibacterial, antiviral, or antifungal agents.

**Infection:** Patients and caregivers should be educated to look for signs and symptoms of infection, which may be subtle because of the immunosuppressive effect of steroids (for example, chills, rigors, and aching rather than a high fever). Obtain blood, urine, sputum, and stool cultures as indicated per institutional protocol, along with chest radiograph and complete blood count with differential. Instruct the patient and his or her caregiver to call the clinician if body temperature is higher than 100.5°F (38°C). Pharmacologic interventions include antibiotics, antiviral agents, or antifungal agents as indicated based on dose and duration of steroid therapy. Prophylactic anti-infective agents for opportunistic infections such as herpes simplex virus, varicella zoster virus, and *Pneumocystis carinii* should be considered. Although prophylaxis against *Pneumocystis carinii* pneumonia and fungal infections is accepted practice, antiviral prophylaxis is controversial (Zitella et al., 2006). Recommendations in the context of neutropenia are discussed in the Nurse Leadership Board’s consensus statement on myelosuppression (Miceli et al., 2008).

**Musculoskeletal Signs and Symptoms**

**Proximal myopathy:** Proximal myopathy is caused by the breakdown of proteins in muscles. Patients should be assessed to determine whether they are candidates for physical therapy exercises that use large muscle groups, or aquatic therapy if weight limits for exercises because of bone involvement in the spine and the risk of compression fracture.

**Avascular necrosis:** Avascular necrosis results from the temporary or permanent loss of blood supply to bones. Although its incidence is low, it is a concern (Talamo et al., 2005). Obtain radiographs or magnetic resonance imaging of the affected and contralateral joints; a high probability exists that the contralateral joint may be affected. Pain assessment with appropriate pharmacologic intervention is needed frequently. Refer promptly to an orthopedist for evaluation, which may result in recommendations for conservative (nonsurgical) or surgical approaches. Consider discontinuation of steroid use.

**Osteopenia and osteoporosis:** Steroids increase bone loss in several ways. They reduce bone formation by inhibiting osteoblasts and increasing osteoblast apoptosis, stimulating bone resorption, inhibiting intestinal absorption of calcium, and increasing urinary excretion of calcium (Lindsay & Cosman, 2005).

A baseline bone density scan should be obtained if other risk factors for osteoporosis are present (e.g., older age, postmenopausal status in women, history of smoking, presence of lytic lesions).

The following are recommendations for the general use of bisphosphonates and calcium supplementation in individuals...
with multiple myeloma, as well as some helpful education tips (Dawson-Hughes, Harris, Krall, & Dallal, 1997; Guise, 2006; Jackson et al., 2006; Lips, Graafmans, Ooms, Bezemier, & Bouter, 1996; Sambrook, 2005).

- Calcium supplementation is advised for patients taking bisphosphonates, particularly zoledronic acid. Nurses should be aware that calcium supplementation is contraindicated in patients with hypercalcemia or significant renal dysfunction, either of which may be present in patients with myeloma.
- The National Osteoporosis Foundation makes the following recommendations for vitamin D intake.
  - Adults younger than 50 need 1,000 mg of calcium and 400–800 IU of vitamin D daily.
  - Adults 50 or older need 1,200 mg of calcium and 800–1,000 IU of vitamin D3.
- Patients taking bisphosphonates should continue with current treatment guidelines.
- Patients should make sure their dental care providers are aware that they are taking bisphosphonates.

Weight-bearing exercise is essential for all patients with osteopenia or osteoporosis and should be advised for most days. Exercise may improve quality of life, muscle strength, and cardiorespiratory function in patients with myeloma (Groeneveldt et al., 2007).

**Muscle cramping:** Although the mechanism of steroid-related muscle cramping is unknown, the symptom may be caused by water retention and fluid or electrolyte shifts. Assess for electrolyte imbalances (sodium, potassium, calcium, and magnesium, which may be altered with the fluid shifts associated with steroids) and replace as needed. Assess for dehydration and replace fluids orally if possible; consider IV fluids if necessary. Muscle relaxants such as baclofen may be considered.

L-glutamine has been noted to be beneficial for muscle cramping. It is a nonessential amino acid that is not synthesized by the body. The mechanism of action is not fully understood but may relate to increased muscle protein synthesis and reduced muscle protein breakdown.
Changes in taste: Taste changes are common with steroid use, but nurses should be aware that they also may occur secondary to oral or sinus infection, decreased or absent saliva production (xerostomia), or GERD. Medications, such as certain antihypertensives, anxiolytics, chemotherapy agents, antibiotics, and zinc, also may cause taste changes, and patients with prior surgery or radiation to the neck may be at increased risk. Removing the underlying cause, if possible, is the treatment of choice, but good oral hygiene and lozenges to stimulate salivary secretions may produce palliative benefit (Doty & Bromley, 2004).

Hiccoughs: Hiccoughs (hiccups, singultus) may respond to well-known home remedies such as holding the breath while drinking water, swallowing a teaspoon of sugar, or drinking from the opposite side of a glass. Pharmacologic interventions include baclofen, chlormpromazine, and phenytoin (Woo-Ming, 2007). When hiccoughs persist, patients should be evaluated for other causes.

Endocrine Signs and Symptoms

Steroid-induced hyperglycemia: Patients should be educated about the signs and symptoms of hyperglycemia and hypoglycemia. Healthcare providers must conduct baseline assessments (Pogach et al., 2004) and refer patients to a primary care physician or endocrinologist if necessary (American Diabetes Association, 2007). Whether strict glycemic control in patients with myeloma has a significant effect on overall outcome is unknown.

• If hyperglycemia is mild, with a postprandial serum blood glucose < 200 mg/dl, and patients do not have a history of diabetes, a nonpharmacologic approach may be adequate. This includes receiving nutrition counseling to avoid simple carbohydrates and sugars, losing weight if overweight, and increasing physical activity.
• If serum glucose is > 200 mg/dl at any time, glucose monitoring with possible oral hypoglycemic agents may be needed.
• If serum glucose is > 300 mg/dl, patients may need insulin therapy at least in the short term, as well as the nonpharmacologic approaches.

Adrenal insufficiency: Acute adrenal insufficiency is characterized by dehydration, hypotension, hypoglycemia, or altered mental status and may occur from rapid cessation of long-term steroid use. Educate patients that it is a potentially life-threatening side effect; tapering steroids after long-term use. If possible, start glucocorticoids at the same dose and increase the dose by 25%–50% each day. If serum glucose is > 200 mg/dl at any time, glucose monitoring with possible oral hypoglycemic agents may be needed. If treatment with oral agents is inadequate, initiation of intravenous glucocorticoids is indicated. Cortisol levels should be obtained (Arlt & Allolio, 2003; Wilson & Speiser, 2007).

Hypogonadism: Hypogonadism occurs when the sex glands produce little or no hormones. This is noted most symptomatically in men who experience a loss of normal male hormone production, with resulting decreases in beard and body hair, muscle loss, and breast enlargement. Women can notice hypogonadism as well, with typical postmenopausal symptoms, such as loss of menstruation, decreased libido, hot flashes, and loss of body hair. Replacing estrogen hormones in women and testosterone in men is controversial but may be a good treatment option depending on the severity of symptoms. Educate patients about the potential for this side effect. Endocrinologists are most appropriate for referral if necessary.

Cardiovascular Signs and Symptoms

Edema: Nonpharmacologic approaches include salt restriction, elevation of limbs, elastic compression stockings, and increased physical activity. If edema is moderate to severe, pharmacologic approaches include diuretics such as hydrochlorothiazide, spironolactone, and furosemide.

Dermatologic Signs and Symptoms

Acneform rashes: Acne-like rashes may occur. When they are mild, recommend that patients wash their faces twice daily with an exfoliant and keep affected areas clean. When rashes are moderate to severe with cystic or infected papules, pharmacologic treatment should be considered (e.g., topical antibiotics such as clindamycin or cephalaxin, oral antibiotics).

Thinning of skin: Skin thinning, skin tearing, and bruising may occur secondary to long-term steroid use. If they occur, suggest good hygiene practices and cleansing of affected areas with sterile water. Patients should be instructed to avoid hydrogen peroxide solutions because they may impair wound healing. Instead, patients should apply triple antibiotic ointment, cover the areas with nonstick gauze for the first five days, and then allow the areas to remain exposed to air to promote healing. Patients also should be advised to avoid trauma by wearing long sleeves and to be cautious during activities to decrease the risk of skin tears.

Conclusions

Corticosteroid therapy can cause mild to severe adverse events that affect almost every body system. However, when patients are followed carefully, and when they and their caregivers are educated about what to expect during treatment, the side effects can be managed effectively to promote adherence to therapy and improve quality of life.

Patient Education Sheet: Managing Steroid-Associated Side Effects of Novel Agents for Multiple Myeloma

**KEY POINTS**

Steroids have been an effective treatment for multiple myeloma, alone and in combination with other drugs, for many years and still are used as an important part of treatment with newer drugs known as novel therapies (thalidomide, lenalidomide, and bortezomib). Steroids cause a wide range of side effects, affecting nearly every system of the body. Identifying the side effects early and managing them quickly will contribute to successful treatment and ultimately improve overall quality of life. Do not stop or adjust your medications without discussing it with your healthcare provider.

Steroids commonly prescribed include dexamethasone, prednisone, prednisolone, and solumedrol.

**POTENTIAL SIDE EFFECTS**

- “Let down” or withdrawal effect
- Flushing and sweating
- Difficulty sleeping (insomnia)
- Sexual dysfunction
- Personality changes or mood alterations
- Hyperactivity and jitters
- Difficulty concentrating
- Increased numbers of white blood cells
- Infection
- Muscle weakness (myopathy)
- Death of bone tissue (avascular necrosis)
- Decrease in bone strength (osteopenia or osteoporosis)
- Muscle cramps
- Weight gain in body or face
- Changes affecting hair
- Blurred vision
- Cataract formation
- Ulcers and heartburn (dyspepsia)
- Gas (flatulence)
- Increased appetite
- Changes in taste
- Hiccoughs
- Higher blood sugar levels
- Temporary diabetes or thyroid issues
- Temporary decrease in testicular size
- Swelling of the hands, legs, or feet
- Acne or rashes
- Thinning of skin

**STRATEGIES FOR CONTINUING TREATMENT**

Steroids should be taken with food.

Steroids can cause sleeplessness and therefore should be taken early in the morning.

Signs and symptoms of infection: fever of more than 100.5°F (38°C), shaking chills even without fever, dizziness, shortness of breath, and low blood pressure

Patients should take an over-the-counter or prescription medication to prevent gastrointestinal issues.

Medications to prevent infection, shingles (small blister-like rash anywhere on the body; usually painful with or without rash), and thrush (white coating on tongue, bad taste, and painful swallowing) also may be prescribed.

Know the signs and symptoms of high and low blood sugar: aggressiveness, confusion, difficulty waking, increased thirst, and frequent urination. If you have known diabetes, consult with your endocrinologist or diabetes educator prior to starting treatment with steroids.

Always report symptoms to your healthcare team as soon as they occur.
